EDITORIAL

I stated in my review of ZEN that there is no APPEND command. This is not true. The LOAD command actually appends the cassette file onto whatever is there. Consequently an APPEND command isn't necessary. Applogies to Laurie Shields for my mistake.

WARNING

48K to 96K RAM UPGRADE

In Issue 4 there was an article on upgrading the user RAM of a 48K Lynx from 16K to 64K. It stated that 4164 RAM chips are needed. It has been pointed out to me that there are two types of 4164 RAMs. There are 7-bit and 8-bit refresh versions and there is no way to tell which Issue 4 is which by looking at the chips. The Lynx requires chips with a 7-bit refresh. I have been told that the TEXAS versions are 8-bit refresh but there may be others. If any one has any more information about which makes work (or which don't) please let me know.

The upgrade article provoked a reaction from Camputers. They would like to point out that your guarantee will become null and void if you upgrade your Lynx.

LETTERS

I have had several letters which contain quite useful pieces of information or ask sensible questions but for one reason or another could not be published without some re-touching. Colin Clayman wrote a letter which was mainly about Eursor Interrupts. Along with the letter he gave a rather useful routine which displays instructions at any time (even if BASIC is doing something else). I feel that its a very good procedure but that it needed a little modification to make it safer and an explanation of how it works.

It works by printing instructions in the alternate green video RAM. You can then display this by disabling the red, blue and normal green banks and enabling the alternate green bank. This is done by an interrupt routine held in a code line. As I explained in the article on Using the BREAK Key (N.N. Issue 3) you have to prevent interrupts during yideo access. This is done by two further routines held in code lines (20 and 30) which disable interrupts for the display driver and the line draw routine. IT IS VERY IMPORTANT TO NOTE THAT ONCE YOU HAVE ENABLED THESE ROUTINES (lines 10120,10130 % 10140) YOU MUST NOT EDIT LINES 10, 20 or 30 OR PUT ANY MORE CODE BETWEEN THESE LINES. The reason for this is that if you do you will move the location of these new routines and the Lynx will 'fall over'. As an example if a line 15 were inserted the display driver routine (line 20) would be 'lost' and the Lynx would crash.

10 CODE F5 3E 14 D3 80 AF 10090 OUT &0086.14 10100 DUT &0087, &003F D3 94 F1 ED 56 FB C9 10110 DPOKE &6294, &45ED 20 CODE F3 CD A4 06 FB C9 10120 DPOKE &6298,LCTN(10) 30 CODE F3 CD BE OF FB C9 40 REM DISPLAY INSTRUCTIONS 10130 DPOKE %6200,LCTM(20) 10140 DPOKE &6263, LCTN(30) 50 PROC HELP 50 REM THE MAIN PROGRAM (dummy) 10150 CALL LCTN(10) 10160 LET K=SETN 100 FOR I=1 TO 20 10170 PROTECT BLACK 120 PRINT I 10180 INK WHITE 140 NEXT I 10190 ENDPROC 160 END 10200 DEFPROC INSTRUCTIONS 19000 DEFPROC HELP 10210 PRINT 'The first line :0040 TEXT of the instructions" 10050 DPGKE &6292,&8000 10060 CLS 10220 PRINT "The second line etc' 10070 PROC INSTRUCTIONS 10230 ENDPROC 10080 DPDKE &6292,&C000

I have had several letters asking the following questions:-

Will software written for the 48K Lynx run on a machine upgraded to 96K? The 48K to 96K RAM upgrade will make no difference to how the software will work. It is the new EPROMS (BASIC version 2) which could cause problems. If software makes direct calls to routines in the EPROMS and the location of these routines change from version to version then the chances are that the software will not run. If the routines are in the same location then there is no problem. If the software makes indirect calls to routines via the RAM vectors then there will be no problem because even if the routine location changes the vector will also change.

To conclude them, it all hangs upon whether software makes direct calls to routines in the EPROMs and whether the locations of the routines have changed. Consequently I would expect most software to run on either machine.

Several people seem to be under the impression that the 'INTERFACE' on the back of the Lynx is a 'port'. Consequently they ask how do you send data to it. The INTERFACE is not a port and the pins can't be used directly.

If you don't understand the pin designations my advice is to leave well alone. You need some extra hardware (joystick interface, parallel printer interface etc) to be able to use the socket.

It seems that some of you don't know how to read and make use of the I/O maps published in Lynx User (ssue 1 (page 22). There are four main columns (or sets of columns) DESCRIPTION, DATA, 1/O ADDRESS and DATA DIRECTION. The DESCRIPTION should need no explanation. The DATA field explains how the external hardware is connected to the ports. Since there are eight bits (binary digits) per port the table gives the connections for each bit. As an example the first line of the keyboard port describes how some of the keys are connected. The SHIFT key is connected to bit 7 (D7), the ESCAPE key is connected to bit 6 (D6), etc. The 1/O ADDRESS column contains the 16-bit address for the port. It is slightly complicated by the fact that not all the address lines are decoded (ie used). Consequently some of the bits may be set as either 0 or 1. These are flagged by asterisks (1). The easiest way of dealing with these is to consider them as zeros. To read the address is quite straightforward as long as you take it in 4-bit nibbles. The first address is '##1# #### #111 1111'. If you change the asterisks to zeros you get '0010 0000 0111 1111'. Now convert each of the 4-bit nibbles into hex (see Machine Code for Beginners - Part 1 if reg). The address then becomes 207FH.

The joystick interface is now available for the Lvnx. The 48K Lynx does not have a JOYSTK command. Can you use joysticks on the 49K machine or do you have to upgrade to the 96K machine? The joysticks are connected to ports 7AH and 7BH. You can read the status of the ports with INP(%7A) and INP(%7B). Now that you have learnt how to read the I/O Maps you will see that the FIRE button is connected to bit 5 and PIGHT, LEFT, DOWN and UP are connected to bits 3 to 0 respectively. All input bits are high (ie set to 1) if there is no input. Hence the following table gives the input values associated with the various operations.

Dear Mr Poate,

Thank you very much for Issue 3 of Nilug News. It makes very interesting reading and I look forward to future issues.

My main purpose in writing is to give you a list of Lynx Software that I have compiled from various sources. This is in response to the request in your Editorial for such information. I hope I am not too late in supplying it.

The list is as complete as I can make it and although you will no doubt know most of the items some of the software may have escaped your notice. There are more tapes available than one might expect but I cannot affirm that it is all still available. Nor can I guarantee that the list is a complete one.

Yours sincerely, A. Rendall.

REVIEWS

GOBBLE DE SPOOK from CAMSOFT

By G. Hindle

This is a fairly good implementation of the old arcade favourite 'PAC-MAN'. Written mainly in machine code (as far as I could tell), it is neat and well thought out.

The game comes neatly packaged in the popular 'Video' type plastic box. On opening the box one finds a cassette and instruction leaflet. Although the leaflet is small it is descriptive and to the point.

To load the game one enters the baud rate is TAPE 0 or 3, followed by RESERVE &6D70. Next comes MLDAD "SPOOK". Both baud rates loaded first time for me on side A, side B has a different recording pattern.

Once loaded the game auto runs commencing with a title page, followed by a menu which is returned to after each game. There are eight levels of play; 1 is the hardest, B the easiest. The controls should be easy to learn. The graphics remind me of early Spectrum graphics and although rather shaky they are effective. Sound is well used considering the limited facilities. It would be nice to be able to switch it off during the menu.

In conclusion, well thought out game with HI-SCORE position and room for three initials, good use of facilities, expensive at £10.00, value eight out of ten.

CONNECT 4 from CAMSOFT

by J.Batty

This is one of the programs in the first batch released by Camsoft. It is a colourful, well-presented version of the game which I am sure eveyone knows. One good feature is that you can choose to play the computer or another person (with the computer as a referee). The computer plays a very good game but even so is beatable and it is very satisfying when you do so. The computer's response is fast (within five seconds), and if you ponder for too long it hurls (friendly) abuse at you! When you win all of his counters obtain sad little faces and they all smile when it wins. There are also a number of sound effects and tunes. I have found that as well as me (age 18) liking it much younger children greatly enjoy it, with the faces and sounds. Altogether, I think that it is very good entertainment and excellent value at £4.95

SPANNERMAN From GEN SOFTWARE

by R.B.Poate

A nuclear reactor is flooding due to leaks in the cooling system. Your job is to stop the leaks and save the reactor. What could be more simple? Unfortunately the drains are blocked and the leaking coolant is flooding the reactor. Furthermore the water disturbs rats which, because they have lived in the reactor for some time, have degenerated into giant anti-matter rats. If you get too

near to them you will die. The final killer is falling girders — all in all not a particularly healthy environment! You have your trusty spanner which you use to tighten the leaking joints and so stop the leaks. One last imaginative point is that if you overtighten the joints they will leak permanently and can't be repaired.

The game starts with you in the centre of a four floor reactor. The floors are connected by ladders. You move using the cursor keys and press the spacebar to make the plumber use the spanner. Additional controls are RETURN to kick the rats and I to jump. The coordination of sound and movement is excellent.

Although the game is fun to play two things spoilt the game for me. Firstly the instructions say that you can give the mutant rats a kick with your steel capped boots. I tried many times but without success. I have since found (after many games) that the timing of the kick is rather critical and that it is better to avoid the rats. The second annoying thing is that the falling girders hit the various floor levels and change direction. You can, for example, have a girder falling vertically on to you. You take a step to the right (or left) only to find that it will hit the floor above your head, change direction and kill you. This means the getting a high score is more a matter of luck rather than skill.

On the whole an excellent game with good sound, graphics, three levels of play and a hall of fame. Overall eight out of ten (nearly nine out of ten).

OH MUMMY from GEM Software Price £7.95 by R.B. Poate

You are the leader of an expedition to explore some newly found pyramids. You search five levels of a pyramid for the Royal Mummies. Guardians protect the pyramids from intruders and these must be avoided. You must find the Royal Mummy and the Key to be able to continue to the next level. If you unearth a Guardian Mummy then it will join the other Guardians which are chasing you.

For me the game depended too much on luck. If you found the scroll, the Key and the Royal Mummy before the lurking Guardian Mummy then you stood a good chance of making a good score. If not you will lose your expedition members. Overall eight out of ten.

SAMES PACK 1 from SEM Software Price f7.95 By R.B.Poate
This games pack has three games on it and after
playing SPANNERMAN and DH MUMMY 1 had a great deal of
trouble loading it. Eventually I decided to look at the
instructions. I found that whereas SPANNERMAN and OH MUMMY
needed to be MLOADed these games had to be LOADed. Once I
had got that sorted out the games loaded first time.

FRUIT MACHINE is the first game. Until I had played it I could never see the point of a fruit machine game -you never lost any money so whats the point? The game has the usual three reels which display the apples, pears, cherries etc. You have optional HOLD and NUDGE if you are lucky and a DOUBLE or RUIT option. You are asked how much money you want to stake and then the game ends when you run out of money or quit. If you have won the program will give you an IOU for your winnings. Its a pity you can't send this off to GEM because I staked a pound to begin with and ended up with eleven and on my second try I staked another pound and ended up with f41.30! I think that the odds are more in your favour than in real life. In spite of the fact that the game is nearly all luck and no skill I liked it

(possibly because I won!).

The second game is TORPEDO and as its name suggests this is about sinking ships with torpedoes. You have a periscope view as a convoy passes by. You try to sink as much tonnage as you can. The ships have funnels and you get most points for a hit below it and less points as the hit moves further away. There are three skill levels and the level determines how many different speeds the ships may have. The skill comes in judging the speed of the ships and in launching your torpedoes at the right time. The game doesn't give you much time to assess the speed of the faster ships so its a game of pure skill.

The final game is MINEFIELD. You have five tanks with which to clear a minefield. They fire proximity shells which explode near mines. You control the tank with the cursor keys and fire shells with the F key. The red tanks are difficult to control at first because they don't respond to normal cursor key directions. The shells are hard to see and could have been made much bigger. I feel that this game was a make-weight becaue its not very good. You can fire a shell across a mine and it doesn't explode. You then move down the path of the shell (thinking it to be safe) only to find that you hit a mine.

Overall quite a fair tape. Value for money seven out of ten.

ROCKETHAN from Bamby Software

By M.LAWSON

This programme was sent to me free by Bamby Software for being patient in waiting for 'Treasure Island'. Very decent of them I thought. There are two games in one, both aimed at children. In the first game you are required to subtract one number from another. Simple! the numbers range from 1 to 99 and the answer is always less than 10. Now for the catches. If you are incorrect you do not get a second chance. From the time the two numbers appear a rocket moves across the screen and every time that a correct answer is received a brick is positioned in a wall, and the rocket starts again. If the rocket crosses the wall, you lose. Once the wall is large enough, another wall is started further across the screen. Eventually the wall is being built right in front of the rocket being launched. All of a sudden panic sets in and adults find that they are not as quick as they thought they were. Well written, good sound and colour, most enjoyable. Aimed at children of 10 and upwards. and adults whose mental arithmetic is rusty.

The second program Factorfire is another mental arith- metic exercise. The idea is to find the highest divisor for a given dividend. The game takes the form of a space ship moving across the screen and 9 lasers on the ground. The space craft bears the dividend and the lasers the divisor. When a number is pressed that will divide exactly,a score of 10 times that number is added to your score. If the divisor is incorrect then 10 times that number is deducted from the score. When those poor Martians get blasted a rather pleasant explosion is observed. Again good colour, good sound, good format. Simple and well thought out. Aimed at anyone old enough to be able to press a number as opposed to a letter. My 4 year old loves this game. On the easiest level of play she has learned to recognise certain numbers and knows the corresponding number to press. i.e.A number ending in 0 or 5 is always divisable by 5. If a number ends in 2 then it will be divisable by 2,etc.etc. In conclusion if you have children it is a good educational game.

XOR PLOTTING By Chris Cytera

Have you ever wondered how ten-line programs for the BBC Microcomputer containing the statement GCDL 3,X manage to produce extraordinarily complex and beautiful patterns? The secret lies in something called exclusive-or plotting, so I will start by explaining what this is.

When the Lynx draws a line on the screen, anything underneath that line is 'pasted over' and forgotten; the new colour is not combined in any way with the colour that previously existed in its place on the screen. It is possible to produce a combination effect by the statement:-PROTECT 7-INK

after every INK statement. This achieves what is known as or-plotting, because the current colour number is effectively logically ored with the colour underneath. However, this effect is not particularly spectacular because the DR operation produces no cancellation; if you attempt to use it to produce complicated patterns then you will end up with a screen containing rather a lot of white.

The exclusive-or operation when applied to binary digits produces a 'l' if one of the two operands is a 'l' but produces a '0' of they are both '1' or both '0'. So, for example, exclusive-oring 010 with 110 results in

If you are unsure about binary numbers, see NILUG NEWS Issue 2, page 5.

If this operation is applied to the Lynx's eight screen colours, some add results occur:-

> RED XOR BLUE gives MAGENTA XOR YELLOW gives GREEN RED RED XOR RED gives BLACK MAGENTA YOR CYAN gives YELLOW

You can check these if you wish by exclusive-oring the binary numbers of each of the colours together. One thing which you should find is that any colour exclusivelyored with itself gives black.

The obvious method of implementing exclusive-or plotting on the Lynx is to rewrite the routine which accesses the screen so that it first reads the screen, exclusive-ors what it finds with what is to be placed there , and then writes the result to the screen.

Unfortunately, this does not work. The reason is that the Lyno's line drawing routine is not accurate enough; when it draws a line, it occasionally plots two dots in the same place. Normally this does not matter, but in exclusive-or mode, the second dot, being the same colour, cancels out the first. The result is a line with gaps in it. Therefore it is also necessary to rewrite the line drawing routine.

However, this opens up an opportunity for optimisation, as the normal line drawing routine is not terribly efficient. For example, consider a horizontal line of eight pixels long, with all the pixels on one screen byte. Normally, the screen is accessed eight times to draw such a line, which seems rather silly when it could be done in one screen access with a massive increase in speed. Also, the screen address and bit pattern are calculated from scratch for each pair of new screen co-ordinates, which is wasteful as they can more quickly be calculated from their previous values. Finally, the standard screen access routine is normally called, which wastes time fiddling around with the

PAPER colour. The value of PAPER is irrelevant when drawing lines, so the new screen access routine ignores it.

The complete machine code program which accomplishes all the above is located at 9900H and occupies 019AH bytes of RAM. Relocation should be no problem provided that all lines referring to the labels 'pattern' and 'screen' are changed (31,42,4E,7E,8D,95,11D). Note that the code MUST be located on a page boundary, and line B2 should be changed so that the B register is loaded with the page number.

When the code has been typed in, save it on cassette. Then try it with:-

DPDKE &6263, &990A POKE &9909.1

Try drawing a few lines. When things are working, save the code again.

You are now ready to try the demonstration programs CARPET and SQUARE DANCE. (To stop the latter, press the space bar. The pattern can then be continued with 'C' or a new one started with 'S').

POKE %9909,1 is used to set exclusive-or mode. To use the new line drawing routine in normal mode, type POKE 19909.0. Make this change to the above-mentioned programs and notice how inferior the results are.

To demonstrate the speed differences try the programs with the usual line drawing routine and the new one. Note the differences in speed, especially for horizontal and near-horizontal lines.

Many other beautiful patterns become possible when exclusive-or plotting is available. Experiment as much as you can - even simple programs can produce spectacular results.

Machine Code For Beginners Part 4

It has ben pointed out to me that the the explanation of Assembler Language in part 3 was a little mis-leading. I stated that conceptually there are four fields. These are LABEL, OPCODE, OPERAND and COMMENT. The example was:-

START LD HL,0 ;zero the HL register pair

I then stated that you would be able to find other examples in the rest of the magazine. This was slightly mis-leading because in the explanation I was talking about INPUT STATEMENTS to an ASSEMBLER whereas the examples published would be output from an assembler. Butput has three extra columns. These are the assembly address, the generated machine code and source code line number. So you might type in:-

LD C.£80 :set C register

and the output might look like:-

800C 0E80 0230 LD C,£80 ;set C register

In this example '800C' is the address where the machine code was assembled, '0E80' is the actual machine code which will load the C register with 80 and '0230' is the line number. The label field is blank, then comes the opcode and operand (LD C,£80) and finally there is the comment field.

Are assembler listings any good to you if you don't have an assembler? As long as you know which part is the machine code and where it has to be assembled you can enter it by using the Monitor M command. As an example consider the following program which sets the INK colour.

The input

00083 880

INK EQU £6258

WHITE EQU 7

LD A, WHITE

LD (INK), A

RET

The output

8000		0010	ORG	000B3
8000	625B	0020 INK	EQU	£625B
8000	0007	0030 WHIT	E EQU	7
8000	3E07	0040	Ł.D	A, WHITE
8002	325B62	0050	LD	(INK),A
8005	£9	0060	RET	

The first thing to note is that lines 20 and 30 generate values in the machine code column (ie 625B and 0007). These values are however all generated at the origin (8000H) and hence don't count as machine code. The first opcode is in fact the '3E' from 'LD A, WHITE'. So if you wanted to enter this code using the Monitor M comand you would type the following:-

>MON [return]
#M8000 [return]
8000 (xx) 3E 07 32 58 62 C9 [return]

Where 'xx' stands for the existing data at location 8000H. I hope that will help you to use the assembler listings published in NILUG NEWS. Now for some more theory.

RESTARTS

When I first started playing with micro-computers, some four years ago, machines where coming onto the market with small amounts of RAM. typically 4 or 8K. Some even had only 1K of RAM. A 16K machine was considered to be guite a large machine. Since memory was expensive and in short supply micro-processor designers gave their products instructions which would save memory. The ISO is no exception. The RESTARTS are one byte call instructions (normal calls require 2 or 3). They allow the program designer to make calls to eight specified locations in memory. So if you were to put very commonly called routines at these places you could save quite a few bytes of memory.

RESTARTS

	Address	65		5568	bler
	1 0000H	NO PROPER			0
[t : CF	-+- ;	RST	8
1 1	+ + 0010H	+ : D7			
1	t	. DF	20		18
<i> </i>	 0020H	t	-#-	OCT	20
l d	+	ŧ			
i n	002BH 		-+-		
1 5	H0500 	ŀ F7 +	¦ -+-	RST	30
į	1 0038H	FF	i i	RST	38

Although you can't use these instructions for general purpose calls they are very useful. It is normal to use them for calling routines which are called very often. Lynx BASIC already uses the Restarts. Unfortunately only three of the restarts are of much use to the machine code programmer.

RST B

RST 8 will output the ASCII character in the A register. For example 50H is the ASCII for the character P. If you load the A register with 50H then use RST 8 the P will appear on the screen.

>10 CODE 3E 50 CF C9 >CALL LCTN(10)[return] P

RST 30

RST 30 jumps to the TRAP routine. This routine saves all the current registers, displays them and then is ready to accept monitor commands. This is how the monitor BREAK-PDINT command works. When you set a breakpoint at a particular address the byte is saved and replaced by F7 (RST 30).

RST 38

RST 38 jumps to 6297H. At 6297H you will find a jump to print the message 'NOT YET IMPLEMENTED'. Since RST 38 jumps to a RAM vector it is possible to use this restart. If you had a particular routine which was called very often in your program it may pay you to reset the RAM vector and use RST 38 instead of a CALL instruction.

LOGICAL INSTRUCTIONS

There are three main logical instructions. These are AND, OR and XOR. Before I discuss these instructions I want to make a point about bad English. I recently saw a sign which said:-

PRIVATE PROPERTY NO PARKING AND TURNING

Now I KNOW what it means but I also know what it says. Its OK if I park there. Its OK if I turn there but they don't want me parking AND turning. I am sure that it should have said 'no parking or turning'.

Not so long ago it was my nephew's birthday. Since he is only 3 I gave him a bottle of pop and gave some money to my sister for him. Would he thank me? no. So my sister said 'either you thank Uncle Robert or you don't have the fizzy'. Although he eventually thanked me as I was leaving I wonder whether my sister would have carried out her threat - I doubt it.

The point is that we use English in a rather slack manner. It doesn't seem to matter to us humans. We seem to understand what is meant even if it is said incorrectly. On the other hand the 280 is absolutely precise in its use of its English words. They mean one thing and one thing only.

AND

The AND instruction performs a bitwise comparison between the A register and the other operand! ie another register, RAM location or data'. If both bits are I then the result is a I. Otherwise the result is a O. Consider ASH AND FOH.

The AND instruction can be used to mask out selected bits. The BEEF command expects the volume in the range of 0 to 63. In actual fact $-c_0$ can give any volume you like. The reason is that the $-c_0$ look at what happens when you AND 255 (maximum B-bit number $-c_0$) it is 3FH you will see why you can set any volume you like.

FFH is 1111 1111 in binary AND 3FH 0611 1111 === ======= 3FH 0011 1111

The IFH acts as a mask and prevents a number larger than 53 being sent to the sound gutput circuitry.

OR

The OR instructions is similar to the AND instruction. It performs a bitwise comparison between the A register and the operand. If one of the bits is a 1 then the result is a 1. Otherwise the result is a 0. Consider ASH AND FOH.

A5H is 1010 0101 in binary

OR FOH 1111 0000 --- ------F5H 1111 0101

Unlike the AND instruction the OR instruction can be used to force the inclusion of set bits in the result. If you have an 8-bit value and you wish to ensure that a particular bit is set you simply OR the original value with a bit pattern that has the appropriate bit set. Suppose you want to ensure that bit 3 is set in a number which (for

example) might be 77H. This is achieved by ORing 77H with 08H. In binary it looks like:-

77H is 0111 0111 in binary

As you can see bit 3 is now set and it will be set regardless of the original number.

All the logical instructions set the zero flag if the result is zero. Consequently you can use the OR instructions to test for zero. Consider a small program to print a string of text.

8000		9910		ORG	£8000
8000	0000	0020	CR	EQU	£00
8000	0000	0030	NULL	EĐU	1)
8000	210980	0050		LD	HL, TEXT-1
8003	73	0060	LOOP	INC	HL
8004	7E	0045		LD.	A, (HL)
9005	B7	0070			A :Test for zero
9008	C8	0080		RET	7
8007	CF	0090		RST	8
8008	18F9	0100		JR	LOOP
800A	54494953	0110	TEXT	DEFM	/THIS IS A MESSAGE/
	20495320				
	41204045				
	53534147				
	45				
801R	0000	0120		DEFB	CR. NULL

If you type this in at 8000H using the M command and then CALL 48000 [return] you will see the message printed on your screen.

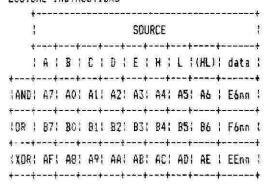

The routine works as follows. Firstly the HL register pair is pointed to the byte before the start of the message. Then we enter a loop to display the characters. The HL register pair is incremented and the A register is loaded with what the HL register pair is pointing to. By oring A with itself the zero flag will be set if the contents of the A register are zero. If the zero flag is set the routine is ended. Otherwise characters to be printed are displayed by the RSI B routine. The loop then continues until the 'O' character at the end of the message (ie NULL) is found.

XOR

XOR stands for exclusive OR and may be considered as an extension of the normal OR. In the normal OR instruction if either bit was a 1 then the result is a 1. Hence if both bits are 1 the result is 1. With the exclusive OR if both bits are 1 then the result is a 0.

AAH is 10101010 in binary XDR F0H 11110000 --- 5AH 01011010

There is one XOR instruction which is used very often. It is 'XOR A'. The A register is exclusively ored with itself. This has the effect of setting A to zero. You could use 'LD A,O' but this takes two bytes instead of the one for XOR A. Furthermore XOR A sets the zero flag whereas LD A,O does not.

BIT MANIPULATION

As well as being able to manipulate bits indirectly with the logical instructions the ZBO provides instructions which permit direct manipulation and testing. These are SET, RESET and BIT. SET allows you to specify that a particular bit be set to a 1. RESET allows you to reset a bit (ie make it a zero). BIT allows you to test a bit. If the bit is zero then the zero flag will be set. Consequently you can use the BIT instruction to control the flow of a program.

The ESCAPE key is connected to bit & of port 0080H. If you set up a loop to test bit 6 of this port you can detect when the ESCAPE key has been pressed.

8000	0010	ORG	B000H
SC00 018000	0020	LD	BC,0080H
8003 ED78	0030 FOOD	IN	A, (C) : READ PORT 0080H
8005 CB77	0040	BIT	6, A : TEST BIT 6
8007 20FA	0050	JR	NZ,LOOP ;ESCAPE?
8009 C9	0060	RET	;RETURN IF IT HAS

You can enter the code via the M command or put it in a CODE line.

> 10 CODE 01 80 00 ED 78 CB 77 20 FA C9 [return] CALL LCTN(10)[return]

Once you call the routine the Lynx will 'hang' until the ESCAPE key is pressed. Try changing the program to test for a different key. After that try testing for two keys to be pressed at the same time.

We have already met one way of ensuring that certain bits are not set when we talked about the BEEP command. Another way would be to use the RES instruction. Hence the first part of the BEEP command could have looked like the following:-

> BEEP RES 7.A RES 5, A

The SET instruction is used in the following program, Zero is loaded to location 9000H. Then bit I of the byte pointed to by the HL register pair is set. After you have run the program examine the contents of location 9000H (use PEEK in BASIC or the Monitor M command).

8000		0010	DRG	8000H
8000	210090	0020	LD	HL, 9000H
8003	AF	0030	XOR	A
8004	77	0040	LD	(HL),A
8005	CBCE	0050	SET	1, (HL)
8007	6.9	0050	RET	

Eight-Bit Subtraction

Eight-bit subtraction takes place between the A register and another register, RAM location or data. The result always ends up in the A register. Binary subtraction is

quite simple since you only have to deal with Os.1s and 2s. Consider the example ASH subtract 73H. If you can remember that AH is ten (decimal) you should be able to see that the result is 32H (10-7 and 5-3). In binary the sum looks like this:-

A5H is 1010 0101 in binary

0111 0011 SUB 73H

0011 0010 32H

Starting at the right-hand side we have 1-1 which is 0. Then 0-1 which can't be done so you borrow TWO (remember its binary). Now we have 2-1=1. In the third column we have 1-0 but you must remember that we had to borrow 1 previously so the sum now becomes 1-1=0. Lastly for the nibble we have 0-0=0. The second nibble is done in a similar way

I can hear you say that I've cheated. What happens with examples like 22H - 77H? The answer is quite simple. You perform the subtraction exactly as before but when you get to the last bits (bits 7) the borrow that you need to make sets the carry flag to indicate that a borrow has taken place (ie in effect the result is negative)

22H is 0010 0010 in binary

SUB 77H 0111 0111

=== -------

1010 1011 and the carry flag will be set. It is easy to see the results of various subtractions by using a simple CODE routine.

10 CODE AF 3E xx 06 yy 90 F7 [return]

CALL LCTN(10) [return]

The xx value is loaded into the A register (opcode 3E) and the vy value is loaded into the B register (opcode 06). The opcode 90 subtracts the B register from the A register and puts the result in the A register. The F7 opcode is a restart which will call the Monitor and display the registers and flags. The registers are as follows:-

AF HL DE BC

AF' HL' DE' BC' IX IY SP PC

Under the registers come the flags. There are eight bits to the F register (ie as normal) but only six bits are used. So far I have only told you about the carry and the zero flags. These are located as follows:-

. Z. C

If the flags are set then you will be given a C or a Z as appropriate. If the flag is not set a dot (.) is displayed.

SUBTRACT WITH CARRY

There is a second subtraction operation known as SUBTRACT MITH CARRY (SBC). This is very similar to the subtract instruction except that the carry flag is involved. The simplest way to consider this instruction is to imagine that the carry flag is subtracted from the result of a normal subtraction operation. Since the carry flag can either be a 1 or a zero there will only be a difference in the result if the carry flag is set. Lets try some examples. Try 55H - 42H with the carry flag set (ie 1).

55H is 0101 0101 SBC 42H 0100 0010 === -------13H 0001 0011 1 4 subtract carry

> 12H 0001 0010

As already noted if the carry flag were zero then it wouldn't affect the result.

COMPARE

It is convenient to put the COMPARE instruction in here. Its operation is the same as a normal subtraction except the A register remains unaltered ie a dummy subtraction is performed. The flags take the results of a normal subtraction. The compare instruction is used to test one 8-bit value against another. There can be three results

- 1. The argument is smaller than the A register. In this case the zero flag and the carry flag will not be set.
- 2. The argument is equal to the A register. In this case the zero flag will be set because the result of the dummy subtraction is zero.
- 3. The argument is larger than the A register. In this case the carry flag will be set because a carry was necessary to enable the subtraction to be performed.

You can try the various combinations with the following little program.

> 10 CODE 3E xx 06 yy B8 F7[return] CALL LCTN(10) [return]

By loading different values into the A register (xx value) and the B register (vy value) you can examine the effects of the comparison on the zero and carry registers.

Sixteen-Bit Subtraction

Sixteen-bit subtraction is done between the HL register pair and another register pair. The result ends up in the HL register pair. There is no normal subtraction only the subtract with carry operation. For this reason it is very common to see XOR A, OR A or AND A before the subtraction since these operations reset the carry flag.

LYNX MACHINE CODE **PROGRAMS**

"ROADER"

A roadrace game with twisting fast road, obstacles, fuel, time and distance display, real time clock, hiscore etc. Fuel consumption increases as you leave the track. How far can you travel and how fast before your fuel runs out or you crash? 100% Machine Code with fast graphics (yes fast) and sound.

"CODER"

This is the assembler we use to write our games. It is also a disassembler, machine code editor, and test tool. What other assembler works with CODE LINES, RAM or ROM, includes a FAST BLOCK PRINT routine to demonstrate BANK SWITCHING, has an integral Disassembler and costs only £7.50?

AND FROM ANDREW GOSLING "TOFDER"

£5 95

A highly addictive version of a favourite arcade game. With 4 levels of play, 11 sheets to clear and hiscore. Deadly enemies such as mutant rubber ducks, submarines, crocodiles, blobmen and harpoons must be avoided to reach the gaps in the coral reef. Once 3 of your "TOES" have reached the gaps in the coral reef they may safely board the waiting boats which then sail off and a new sheet appears. Each sheet becomes progressively harder. 100% machine code with fast graphics (yes fast) and sound.
